Description

Technical Field

- 5 **[0001]** The present invention relates to novel compounds or salts thereof having inhibitory action on VLA-4 (Very Late Antigen-4), and medicaments having these compounds as an effective ingredient.

Background Art

- 10 **[0002]** A main pathological feature of inflammatory and autoimmune diseases resides in accumulation of activated leukocytes on a damaged tissue (inflamed tissue). A process of leukocytes from migration out of the circulatory system to transmigration on the inflammatory site involves four-step cascade reactions which interact each other: (1) adhesion and rolling, (2) activation, (3) firm adhesion and (4) transmigration (Springer, T., *Ann. Rev. Physiol.*, 57: 827 (1995)).

- 15 **[0003]** First, leukocytes adhere to the vascular endothelium to a slight degree and roll on its surface. Then, activation of cells mediated by soluble chemoattractants occurs, which starts formation of firmer bonding between leukocytes to vascular endothelial cells. This firm bonding successively causes adhesion and transmigration of leukocytes across the space between the vascular endothelial cells. These steps occur continuously and each step is indispensable for occurrence of leukocyte transmigration. This also suggests that leukocyte transmigration is controlled at each step.
20 This fact provides many interesting themes from the viewpoint of pharmaceuticals.

- [0004]** A number of receptors in vivo are known. Among them, receptors taking part in leukocyte transmigration are characterized in that they belong to the cell adhesion molecule family (Carlos and Harlan, *Blood*, 82: 2068(1994)). The initial adhesion and rolling are mediated by an adhesion receptor called "selectin". Firm adhesion is mediated by mutual action between integrins on the leukocyte surface and immunoglobulin superfamily molecules expressed on the vascular endothelial surface. Both of these integrins and immunoglobulin type adhesion molecules mainly participate in leukocyte transmigration. Whether leukocytes pass through the extracellular matrix or stop at the inflammatory site after transmigration depends on integrins.

- [0005]** Integrins are a large family of heterodimeric glycoproteins in each of which two non-equivalent α and β -subunits are associated (Heynes, R., *Cell*, 69: 11(1992)). There exist at least 16 α -subunits (α -1 to α -9, α L, α M, α D, α X, α E, α IIb, α V) which are different each other and at least 9 β -subunits (β -1 to β 9) which are different each other. Integrins are classified into subfamilies based on β -subunits. Leukocytes express many different integrins including α 4 β 1, α 5 β 1, α 6 β 1, α 4 β 7, α L β 2, α X β 2 and α V β 3.

- [0006]** The integrin α 4 β 1 is known as a very late antigen (very late antigen-4; VLA-4) or CD49d/CD29. It is expressed by monocytes, lymphocytes, eosinophils and basocytes and serves as a modification factor to be a key in various inflammatory deficiencies (Helmer, M. *Ann. Rev. Immunol.*, 8: 365(1990)). The integrin α 4 β 1 functions as a receptor for vascular cell adhesion molecule-1 (VCAM-1) and also as a receptor for fibronectin (FN) of extracellular protein (Elices, *et al.*, *Cell*, 60: 577(1990)).

- [0007]** In recent years, it has been proved by the below-described studies that selective inhibition against adhesion mediated by α 4 β 1/VCAM-1 will become a solving means for the treatment of autoimmune and allergic inflammatory diseases.

- [0008]** Described specifically, an in vivo experiment has proved that a monoclonal antibody which blocks the pathway of α 4 β 1/VCAM-1 has anti-inflammatory effects and retards the progress of the diseases (Lobb *et al.*, *J. Clin. Invest.*, 94: 1722-28(1994)). In addition, reported are suppression, by an anti- α 4 antibody, of both antigen-induced airway hypersensitivity and accumulation of leukocytes in airway alveolar secretion in guinea pigs used a pulmonary inflammation model (Pretolani, *et al.*, *J. Exp. Med.*, 180: 795(1994); suppression, by α 4 or VCAM-1 antibody, of eosinophil transmigration on the airway of mice used as an antigen-induced model (Nakajima *et al.*, *J. Exp. Med.*, 179: 1145 (1994)), retardation or suppression, by α 4 or VCAM-1 monoclonal antibody treatment, of onset of delayed dermal hypersensitivity in mice and monkeys (Chisholm *et al.*, *Eur. J. Immunol.*, 179: 1145(1994), Silber *et al.*, *J. Clin. Invest.*, 93: 1554(1993)); a model of cardiac transplantation rejection due to (incidental to) specific immunosuppressive action (Isobe *et al.*, *J. Immunol.*, 153: 5810(1994)); graft versus host disease after bone marrow transplantation in mice (Yang *et al.*, *Proc. Natl. Acad. Sci. USA*, 90: 10494(1993)); and experimental autoimmune encephalomyelitis in rats and mice (Yednock, *et al.*, *Nature*, 356: 63(1992), Baron, *et al.*, *J. Exp. Med.*, 177: 57(1993)).

- [0009]** In addition, there is a report on significant retardation of the onset of diabetes by administration, to nonobese diabetic mice used as an in vivo model, of soluble VCAM-immunoglobulin (Ig) fusion protein prepared by fusing two human N-terminal regions to the common portion of human IgG1 in accordance with Rational Drug Design (Significant delays the onset of adoptively transferred autoimmune diabetes in nonobese mice (Jakubowski *et al.*, *J. Immunol.*, 155: 938(1995)). Another report is that as a result of synthesis of a cyclic peptide antagonist by using the three-dimensional crystal structure of a VCAM-1 fragment for mimicking the binding loop portion of α 4 integrin at the domain-1 of

VCAM-1, CQIDSPC of the synthesized VCAM-1 peptide succeeded in inhibiting adhesion of VLA-4 expressed cells to purified VCAM-1 (Wang *et al.*, *Proc. Natl. Acad. Sci. USA*, 92: 5714(1995)).

[0010] Reported as another strategy are blocking of adhesion of $\alpha 4\beta 1$ to either one of binding sites of its corresponding receptor, that is, fibronectin including connecting segment-1 (CS-1) domain (E.A. Wayner, *J. Cell. Biol.*, 116: 489 (1992)); and in vitro inhibition, by synthetic CS-1 tetrapeptide (phenylacetic acid-Leu-Asp-Phe-d-Pro-amide), of leukocyte adhesion mediated by VLA-4 and amelioration of advance of coronary arterial diseases in cardiac transplantation of rabbits (Molossi *et al.*, *J. Clin. Invest.*, 95: 2601(1995)).

[0011] In addition, there are several reports on compounds exhibiting in vitro VLA-4 inhibitory activity (U.S. Patent No. 5,821,231, WO96/22966, WO97/03094, WO98/0424 and WO98/04913).

[0012] Medicaments exhibiting sufficient effectiveness in oral administration and having clinical utility however have not yet been found.

[0013] An object of the present invention is therefore to provide a medicament which serves a selective inhibitor against VLA-4, exhibits effectiveness by oral administration and is administrable for a long period of time.

For example, the alcohol derivative (22) can be prepared by, after acidic or alkaline hydrolysis of the ester derivative (20) into the corresponding carboxylic acid (21), treating the resulting compound with borane or a reducing agent of such a kind in an inert halogenated hydrocarbon solvent such as methylene chloride, an inert hydrocarbon solvent such as toluene or an inert ether solvent such as tetrahydrofuran at a temperature range of from -20°C to the boiling point of the solvent, preferably from 0°C to the boiling point of the solvent. In this reduction, a preferable protecting group must be introduced as E of the ester derivative (20) and a tertiary butyloxycarbonyl group is preferred as it. Alternatively, the alcohol derivative (22) can be prepared not via the carboxylic acid (21) but directly from the ester derivative (20). For example, the alcohol derivative (22) can be prepared by treating the ester derivative (20) with a reducing agent such as diisobutyl aluminum hydride in an inert ether solvent such as tetrahydrofuran, preferably in an inert hydrocarbon solvent such as toluene or an inert halogenated hydrocarbon solvent such as methylene chloride at a temperature range of from -78°C to the boiling point of the solvent, preferably from 0°C to room temperature. Also in this case, a preferable protecting group must be introduced as E of the ester derivative (20) and, as it, a tertiary butyloxycarbonyl group is preferred. After formation of an ether bond by the Mitsunobu reaction with a phenol such as methyl 4-hydroxybenzoate and introduction of an aryl group or a heteroaryl group are conducted simultaneously, the protecting group E is removed. When E is a tertiary butyloxycarbonyl group, deprotection is performed by treating with trifluoroacetic acid in a solventless manner or in an inert halogenated hydrocarbon solvent such as methylene chloride, whereby the compound of the formula (2a) can be prepared. The ether bond formation of the compound (23) from the compound (22) can be conducted, instead of the above-described Mitsunobu reaction, by converting the primary hydroxy group of the compound (22) into an eliminating group such as mesyloxy group and then treating the resulting compound with a phenol such as methyl

4-hydroxybenzoate in an inert polar solvent such N,N-dimethylformamide at a temperature range from 0°C to 90°C in the presence of an inorganic base such as sodium hydride or potassium carbonate. In this case, a preferable protecting group E, for example, is a benzyloxycarbonyl group.

[0117] When Z₃ of the compound (23) is an phenylene group, a cyclohexane derivative (24) can be prepared by nuclear reduction of the benzene ring in a known manner. For example, a reduced derivative (24) can be prepared by catalytic hydrogenation of a compound of the formula (23) in an inert alcohol solvent such as methanol in the presence of a catalyst such as palladium, platinum oxide, preferably rhodium at 1 to 1000 atm, preferably 1 to 100 atm under a hydrogen atmosphere (R.A.Finnegan *et al.*, *J. Org. Chem.*, 30, 4145 (1965); A.I.Meyers *et al.*, *Org. Synth.*, 51, 103 (1971)). The above-described reduction is preferably conducted in the presence of acetic acid or trifluoroacetic acid. The protecting group E is then removed, for example, by treating, when E is a tertiary butyloxycarbonyl group, with trifluoroacetic acid in a solventless manner or an inert halogenated hydrocarbon solvent such as methylene chloride, whereby a compound of the compound (2b) can be prepared. The compound (2b) is also available by deprotection of E from the compound (23), followed by the above-described reduction.

[Scheme 5]

[0118] In the below-described (Scheme 5a), shown is a process permitting preparation of compounds of the formulas (3a) and (3b) in accordance with the preparation process of (Scheme 5) by using, as a raw material, a compound of the formula (22a) which is available commercially or in a known manner. Or, a primary alcohol derivative can be prepared in a known manner, for example, by converting the secondary hydroxy group of the compound (3a) into an eliminating group such as mesyloxy group, converting it into a cyano group by acting a cyanation agent such as potassium cyanide, then converting it into a formyl group by using diisopropyl aluminum hydride, and effecting reduction by sodium borohydride. An compound which is extended by one carbon between oxygen atom and ring in the compound (3b) can be prepared by using the resulting primary alcohol derivative as a raw material in accordance with the above-described ether bond formation method (A.Tarnowsky *et al.*, *Bioorg. Med. Chem. Lett.*, 7, 573 (1997)).

[Scheme 5a]

[0119] In the below-described (Scheme 6), indicated is a process for preparing a sulfide, sulfoxide or sulfone derivative (2m) in a known manner by using the alcohol derivative (22) as a starting material.

[0120] For example, a compound of the formula (25) can be prepared by converting a primary hydroxyl group of the alcohol derivative (22) into an eliminating group such as mesyloxy group and then treating the resulting compound with a thiol, which is available commercially or in a known manner, in an inert ether solvent such as tetrahydrofuran, an inert halogenated hydrocarbon solvent such as methylene chloride, preferably in an inert polar solvent such as N, N-dimethylformamide at a temperature range of from $-20^{\circ}C$ to the boiling point of the solvent, preferably from room temperature to the boiling point of the solvent in the presence of a base such as potassium carbonate or sodium hydride. By subjecting the resulting compound to known oxidation reaction, its sulfide portion can be converted into a sulfoxide or sulfone group.

[0121] For example, the compound (25) can be converted into the corresponding sulfoxide or sulfone derivative by treating it with commercially available 3-chloroperbenzoic acid or peroxide such as hydrogen peroxide in an inert halogenated hydrocarbon solvent such as methylene chloride at a temperature range of from $-78^{\circ}C$ to the boiling point of the solvent, preferably from $-20^{\circ}C$ to room temperature. The protecting group E is then removed from the compound (25), or sulfoxide or sulfone derivative thereof, whereby a compound (2m) can be prepared.

(Scheme 6)

[0122] In the below-described (Scheme 7), a process for preparing compounds of the formulas (2c) and (2d) including a step of forming an amide bond is indicated. An amide derivative (27) or (29) can be prepared by reacting the carboxylic acid derivative (21) and a chain amine (26) or cyclic amine (28), which is available commercially or in a known manner, by using a condensing agent such as 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide hydrochloride, N,N-dicyclohexylcarbodiimide or N,N-carbonyldiimidazole or an analogue thereto in an inert halogenated hydrocarbon solvent such as methylene chloride, an inert hydrocarbon solvent such as toluene, an inert ether solvent such as tetrahydrofuran or an inert polar solvent such as N,N-dimethylformamide at a temperature range of from $-20^{\circ}C$ to the boiling point of the solvent, preferably from $0^{\circ}C$ to room temperature. This reaction can also be conducted in the presence of an organic amine base such as triethylamine or N,N-dimethylaminopyridine, or the organic amine base and 1-hydroxy-benzotriazole. By deprotection of E , the compound of the formula (2c) or (2d) can be prepared.

[Scheme 7]

[0123] In the below-described (Scheme 8), a preparation process of a compound of the formula (2e) or (2f) including an N-alkylating step is indicated. The alcohol derivative (22) in (Scheme 5) can be converted into the corresponding aldehyde derivative (31) by oxidizing a primary hydroxyl group into an aldehyde in a known manner. For example, oxidation using a chromic acid, or oxidation using dimethylsulfoxide, for example, Swern oxidation is usable for conversion. The resulting aldehyde derivative (31) is then subjected to reductive N-alkylation reaction with the above-described amine derivative (26) or (28) in a known manner. This reducing reaction can be conducted using a reducing agent such as sodium cyanoborohydride or triacetoxy sodium borohydride in an inert alcohol solvent such as methanol or an inert ether solvent such as tetrahydrofuran. When sodium cyanoborohydride is used, reaction is preferably conducted under acidic conditions, for example, in the presence of acetic acid. The N-alkylation reaction can also be conducted by catalytic hydrogenation using a commercially available catalyst such as palladium-carbon. By the de-protection of protecting group E from the reduced derivative (32) or (34), a compound of the formula (2e) or (2f) can be prepared.

[Scheme 8]

[0124] In the below-described (Scheme 9), indicated is a preparation process of the compounds of the formulas (2g), (2h) and (2i) which are compounds of the formula (2) wherein Ys are a carbon-carbon triple bond (ethynyl group), a carbon-carbon double bond (vinyl group) and a carbon-carbon single bond (ethyl group), respectively.

[Scheme 9]

[0125] An acetylene derivative (35) can be prepared from the compound (31) in accordance with a known triple bond forming reaction, for example, by reacting trimethylsilyldiazomethane with a base such as lithium diisopropylamide in an inert ether solvent such as tetrahydrofuran at a temperature range of from -78°C to the boiling point of the solvent and then reacting the resulting compound with the above-described aldehyde derivative (31) (Y.Ito *et al.*, *Synlett*, 1163 (1997)). The acetylene derivative thus obtained is then reacted, in a known manner, with an aryl halide derivative or trifluoromethylsulfonyloxyaryl derivative, which is available commercially or in a known manner, in the presence of a palladium catalyst such as tetrakis(triphenylphosphine) palladium or palladium acetate and an organic base such as diisopropylamine or an inorganic base such as potassium carbonate in an inert polar solvent such as N,N-dimethylformamide at a temperature range of from -20°C to the boiling point of the solvent, preferably from 0°C to the boiling point, whereby the corresponding ethynyl derivative (36) can be prepared (T.Eckert *et al.*, *Synth. Commun.*, 28, 327 (1998)). By deprotection of E from the resulting derivative, a compound of the formula (2g) can be prepared. As the preferable protecting group E, a tert-butoxycarbonyl group can be exemplified.

[0126] A vinyl derivative (38) is available in a known manner by using the above-described aldehyde derivative (31) as a raw material. The compound of the formula (38) can be prepared by reacting a Wittig-Horner reagent, which is available commercially or in a known manner, with a base such as lithium hexamethyldisilazane in an inert ether solvent such as tetrahydrofuran at a temperature range of from -78°C to the boiling point of the solvent, preferably from -78°C to room temperature and then reacting the resulting compound with the aldehyde derivative (31). Then, by deprotection of E, the compound of the formula (2h) can be prepared. Alternatively, the vinyl derivative (38) is available by subjecting the above-described ethynyl derivative (36) used as a raw material to known reducing reaction. For example, the ethynyl derivative (36) is subjected to catalytic hydrogenation in an inert alcohol solvent such as ethanol in the presence of a Lindlar catalyst and an organic amine base, such as quinoline, serving as a catalytic poison, whereby the vinyl derivative (38) can be prepared. Also upon preparation of the vinyl derivative, a preferable protecting group E must be used and as it, a tertiary butoxycarbonyl group is preferred.

[0127] An ethyl derivative (39) is available by catalytic hydrogenation of the ethynyl derivative (36) or vinyl derivative (38) used as a raw material. Then, the protecting group E is removed, whereby the compound of the formula (2i) can be prepared. Alternatively, the compound of the formula (2i) can be obtained by catalytic hydrogenation of the ethynyl derivative (2g) or vinyl derivative (2h).

[0128] In the below-described (Scheme 10) to (Scheme 13), a preparation process of a pyrrolidine is shown as a specific example of a preparation process of the compound of the formula (20) used as a raw material in (Scheme 5) (in the schemes, R³⁰ represents a lower alkyl group, R³¹, R³³, R³⁶ and R³⁴ each independently represents a substituted or unsubstituted alkyl group, a substituted or unsubstituted aryl group or a substituted or unsubstituted heteroaryl group, X⁵ represents a cyano group, an amino group, an azide group, a halogen atom, a substituted or unsubstituted

monoalkylamino group, a substituted or unsubstituted dialkylamino group, a substituted or unsubstituted cycloalkylamino group, a substituted or unsubstituted alkylsulfonylamino group, a substituted or unsubstituted allyloxy group, a substituted or unsubstituted alkylthio group, a substituted or unsubstituted alkylsulfoxide group or a substituted or unsubstituted alkylsulfone group and E has the same meaning as described above).

[0129] In the below-described (Scheme 10), shown is a preparation process of a compound having a substituent introduced into the 4-position of pyrrolidine. An ester derivative (41) can be prepared by reacting commercially available 4-hydroxy-L-proline (40) with methanol hydrochloride, for example, at a temperature range of from room temperature to the boiling point of the solvent. The resulting ester derivative is then treated in an inert polar solvent mixture such as water and acetonitrile in the presence of an acid anhydride such as di-tert-butyl dicarbonate, an acyl-halide such as benzyloxycarbonyl chloride, an organic amine base such as triethylamine or an inorganic base such as potassium carbonate, whereby a compound of the formula (20a) can be prepared. The secondary hydroxyl group of the alcohol derivative (20a) can be converted into a secondary hydroxyl group having a contrary steric configuration by the Mitsunobu reaction. For example, the alcohol derivative (20a) and formic acid are subjected to the Mitsunobu reaction to introduce a formyloxy group into the secondary hydroxyl group portion, followed by alkaline hydrolysis by using an inorganic base such as potassium carbonate, preferably sodium bicarbonate, whereby the compound (20b) can be prepared.

(Scheme 10)

[0130] Alkoxy derivatives (20c) and (20d) can be prepared by treating the secondary hydroxyl group portion of the alcohol derivatives (20a) and (20b) in a known manner or while maintaining the steric structure in a known manner. For example, the alkoxy compounds (20c) and (20d) can be prepared by treating the alcohol compounds (20a) and (20b) in an inert ether solvent such as tetrahydrofuran or an inert polar solvent such as N,N-dimethylformamide at a temperature range of from -20°C to the boiling point of the solvent, preferably from -20°C to room temperature in the presence of an alkyl halide such as methyl iodide or benzyl bromide and an inorganic base such as sodium hydride. When the corresponding benzyloxy derivative is prepared by the above-described alkylation, it is preferred to add an inorganic base to the reaction mixture in the final stage of reaction at a temperature range of from -20°C to room temperature. A compound of the formula (I) having a hydroxy group at 4-position of the pyrrolidine ring can be prepared, for example, by protecting the 4-hydroxyl group of the pyrrolidine ring of the compound (20a) or (20b) with a tertiary butyldimethylsilyl group and then using the resulting compound as a raw material.

[0131] By known S_N2 type nucleophilic displacement reaction of the secondary hydroxyl groups of the compounds (20a) and (20b), these compounds can be converted into the compounds (20e) and (20f), respectively. For example, a fluorine atom can be introduced by treating, for example, the compound (20a) with a fluorinating agent such as

diethylaminosulfur trifluoride in an inert halogenated hydrocarbon solvent such as methylene chloride at a temperature range of from -78°C to the boiling point of the solvent, preferably from 0°C to room temperature (L.Demange *et al.*, *Tetrahedron Lett.*, 39, 1169 (1998)).

Alternatively, a fluorine atom can be introduced by converting the secondary hydroxyl groups of the compounds (20a) and (20b) into an eliminating group such as alkyl or arylsulfonyloxy group, e.g., mesyloxy group and then treating the resulting compound with a fluoride of an alkali metal such as potassium fluoride or a fluoride of an alkaline earth metal such as cesium fluoride in an inert polar solvent such as N,N-dimethylformamide or ethylene glycol (G.Giardina *et al.*, *Synlett*, 1, 57 (1995)). A cyano group can be introduced into the mesyloxy derivative by acting thereon a cyanation agent such as potassium cyanide. The secondary hydroxyl group of each of the compounds (20a) and (20b) can be converted into a chlorine atom by reacting it with triphenylphosphine in a carbon tetrachloride solvent at a temperature range of from -20°C to the boiling point of the solvent, preferably from room temperature to the boiling point of the solvent (T.R.Webb *et al.*, *J. Org. Chem.*, 56, 3009 (1991)). It can also be converted into a phenoxy or phthaloyl group by the Mitsunobu reaction. This phthaloyl group can be converted into an amino group in a known manner by treating it with a commercially available hydrazine hydrate in an inert alcohol solvent such as ethanol. Furthermore, this amino group can be converted into a monoalkylamino or dialkylamino group by the above-described reductive amination reaction or treatment with a carbon halide such as iodomethane in the presence of an organic amine base such as triethylamine or an inorganic base such as potassium carbonate.

[0132] The above-described conversion into an amino group can be conducted by an alternative process. For example, after conversion of the secondary hydroxyl group of each of the compounds (20a) and (20b) into an eliminating group such as mesyloxy group, the compound is treated with lithium azide or sodium azide in an inert polar solvent such as N,N-dimethylformamide or inert ether solvent such as tetrahydrofuran at a temperature range of from -20°C to the boiling point of the solvent, whereby the corresponding azide derivative can be obtained. It is then treated with triphenylphosphine and water in a known reducing method in an inert ether solvent such as tetrahydrofuran at a temperature range of from -20°C to the boiling point of the solvent, preferably from room temperature to the boiling point of the solvent, or is subjected to catalytic hydrogenation or reduction with a reducing agent such as sodium borohydride in a known manner to convert the group into an amino group. An introduction of substituent at the 3-position of pyrrolidine ring can also be conducted by using commercially available trans-3-hydroxy-L-proline as a raw material in accordance with the manner described in (Scheme 10).

[0133] In the below-described (Scheme 11), a process for preparing dehydropyrrolidine (20g) in a known manner is indicated. For example, a 3,4-dihydropyrrolidine derivative (20g) can be prepared by converting the secondary hydroxyl group of the derivative (20a) into an eliminating group such as a mesyloxy group or bromine atom, preferably iodine atom, and then treating the resulting compound with an organic amine base such as 1,8-diazabicyclo(5,4,0)-7-undecene. Alternatively, the 3,4-dihydropyrrolidine derivative (20g) can be prepared by converting the secondary hydroxyl group of the derivative (20a) into the above-described eliminating group, treating with phenylselenenyl sodium, which has been prepared from diphenyl diselenide and sodium borohydride, in methanol and then treating with a peroxide such as hydrogen peroxide in methylene chloride in the presence of pyridine (H.Rueger *et al.*, *Can. J. Chem.*, 60, 2918 (1982)).

[Scheme 11]

[0134] In the below-described (Scheme 12), a process for preparing a 3,4-dihydroxy derivative (20h) and a 3,4-dialkoxy derivative (20i) in a known manner by using, as a raw material, the compound (20g) shown in (Scheme 11) is specifically indicated.

[0135] The compound (20g) can be converted into its corresponding 3,4-dihydroxy derivative (20h) by treating it with a commercially available oxidizing agent such as 4-methylmorpholin-4-oxide derivative and osmium tetroxide in a mixture of an inert polar solvent such as acetone with water or an inert ether solvent such as tetrahydrofuran with water, at a temperature range of from -20°C to the boiling point of the solvent, preferably from 0°C to room temperature.

Then, the resulting compound can be converted into a dialkoxy derivative (20i) by treating with an alkyl halide such as methyl iodide or benzyl bromide in the presence of an inorganic base such as sodium hydride in an inert polar solvent such as N,N-dimethylformamide. Or, a derivative (20i) having a cyclic acetal or cyclic ketal introduced therein can be prepared by treating with a commercially available ketalization agent or acetalization agent in an inert polar solvent such as N,N-dimethylformamide or an inert halogenated hydrocarbon solvent such as methylene chloride in the presence of an organic acid such as tosylic acid (J.E.Baldwin *et al.*, *Tetrahedron Lett.*, 35, 4649 (1994); D.M.Goli *et al.*, *Carbohydr. Res.*, 259, 219 (1994)). The above-described ketal or acetal is usable as a protecting group for the secondary hydroxyl group at the 3,4-position. The ketal or acetal derivative can be used as a raw material for the preparation of a compound of the formula (I) having 3,4-dihydroxypyrrolidine.

[Scheme 12]

[0136] In the below-described (Scheme 13), a process for preparing a derivative (20j) having a substituent introduced at the 5-position of pyrrolidine in a known manner is indicated. For example, a commercially available N-(tertiary butyloxycarbonyl)-L-pyroglytamate ester (42) can be converted into the corresponding ring-opened derivative (43) by treating with an organolithium reagent such as phenyl lithium or a Grignard reagent such as methyl magnesium bromide in an inert ether solvent such as tetrahydrofuran at a temperature range of from -20°C to the boiling point of the solvent, preferably from -20°C to room temperature.

[0137] Then the resulting derivative can be converted into the corresponding cyclic imine derivative (44) by treating under acidic conditions, preferably, with trifluoroacetic acid to remove the tertiary butyloxycarbonyl group. By catalytic hydrogenation of the resulting compound, the corresponding pyrrolidine derivative (20j) having a 2,5-cis configuration can be prepared (J.V.Betsbrugge *et al.*, *Tetrahedron*, 54, 1753 (1998)). It can also be prepared by, instead of catalytic hydrogenation, reduction of imine with a reducing agent such as sodium cyanoborohydride. A pyrrolidine derivative having a 2,5-trans configuration can be prepared, for example, by using commercially available benzyl glycidyl ether as a starting material in accordance with Takano's procedure (S.Takano *et al.*, *Tetrahedron Lett.*, 30, 3805 (1989)).

[Scheme 13]

[0138] In the below-described (Scheme 14) to (Scheme 18), a process for preparing the compound of the formula (4) serving as a raw material in (Scheme 1) from commercially available amino acid, for example, glycine, is shown (in these schemes, E, R²⁰, R¹⁰, R²⁸, Z³, Z⁴, A², X⁴, n¹ and R¹⁹ have the same meanings as described above).

[0139] The below-described (Scheme 14) indicates that compounds of the formulas (4a), (4b) and (4c) can be synthesized in accordance with the preparation process as shown above in (Scheme 5) and (Scheme 6) by using as a raw material a glycine derivative (45) which can be prepared in a known manner.

[Scheme 14]

[0140] The below-described (Scheme 15) indicates that compounds of the formulas (4d) and (4e) can be prepared in accordance with a preparation process shown in (Scheme 7) by using the above-described glycine derivative (45) as a raw material.

[Scheme 15]

[0141] The below-described (Scheme 16) indicates that compounds of the formulas (4f) and (4g) can be prepared in accordance with a preparation process as shown in (Scheme 8) by using the above-described alcoholic derivative (46) as a raw material.

[Scheme 16]

[0142] The below-described (Scheme 17) indicates that compounds of the formulas (4h), (4i) and (4j) can be prepared in accordance with a preparation process as shown in (Scheme 9) by using the above-described alcohol derivative

(46) as a raw material.

[Scheme 17]

[0143] The below-described (Scheme 18) indicates that a primary amine (48) which is available commercially or in a known manner can be converted into a compound of the formula (4k) in accordance with the reductive N-alkylating reaction as shown in (Scheme 8) by reacting the primary amine with an aldehyde derivative (49) which is available commercially or in a known manner.

[Scheme 18.]

Example 1

4-((4S)-Fluoro-1-(2-phenylamino-6-benzoxazolylacetyl-(2S)-pyrrolidinylmethoxy)benzoic acid:

(Step 1) Synthesis of methyl 2-phenylaminobenzoxazol-6-acetate

[0153]

[0154] In ethanol (10 ml) was dissolved methyl 3-hydroxy-4-nitrophenylacetate (592 mg, 2.81 mmol), followed by the addition of 5% palladium/carbon (194 mg). The resulting mixture was subjected to catalytic hydrogenation overnight under stirring at room temperature and normal pressure. After removal the catalyst from the reaction mixture by filtration through Celite under reduced pressure, the filtrated cake was washed with ethanol (30 ml). The filtrate was stirred at room temperature. After addition of phenyl isothiocyanate (370 μ l, 3.09 mmol) and stirring at room temperature for one hour, mercuric oxide (yellow) (1.1 g, 5.07 mmol) was added. The reaction mixture was heated under reflux for 3 hours. The mixture was then cooled and the insoluble matter was filtered out under reduced pressure. The filtrate was distilled under reduced pressure. The residue was purified by chromatography on a silica gel column, whereby methyl 2-phenylaminobenzoxazol-6-acetate (480 mg, 61%) was obtained as a white solid from chloroform-ethyl acetate (10:1, v/v) eluate fractions.

$^1\text{H-NMR}$ (CDCl_3) δ : 3.69 (s, 2H), 3.70 (s, 3H), 7.11 (m, 2H), 7.24 (m, 1H), 7.30 (s, 1H), 7.50-7.38 (m, 3H), 7.59 (d, $J=1.2\text{Hz}$, 2H).

(Step 2) Synthesis of 2-phenylaminobenzoxazol-6-acetic acid

[0155]

[0156] In tetrahydrofuran (which will hereinafter be abbreviated as "THF") (2 ml) and methanol (2 ml) was dissolved methyl 2-phenylaminobenzoxazol-6-acetate (460 mg, 1.63 mmol), followed by the addition of 1N NaOH (3.3 ml) under stirring at room temperature. After further stirring overnight at room temperature, the reaction mixture was concentrated into a small volume. The concentrate was acidified with acetic acid. The crystals thus obtained were collected by filtration, washed with water and then dried, whereby 2-phenylaminobenzoxazol-6-acetic acid (348 mg, 80%) was obtained as a pale yellow solid.

$^1\text{H-NMR}$ (DMSO-d_6) δ : 3.64 (s, 2H), 7.03 (t, $J=7.6\text{Hz}$, 1H), 7.11 (dd, $J=1.2, 8.0\text{Hz}$, 1H), 7.35-7.40 (m, 4H), 7.76 (d, $J=8.8\text{Hz}$, 2H), 10.60 (brs, 1H), 12.4 (br, 1H).

(Step 3) Synthesis of methyl 4-((4S)-fluoro-1-(2-phenylamino-6-benzoxazolylacetyl)-(2S)-pyrrolidinylmethoxy)benzoate

[0157]

[0158] In N,N-dimethylformamide (which will hereinafter be abbreviated as "DMF") (12 ml) were dissolved 2-phenylaminobenzoxazol-6-acetic acid (309 mg, 1.15 mmol) and methyl 4-((4S)-fluoro-(2S)-pyrrolidinylmethoxy)benzoate (292 mg, 1.15 mmol), followed by the addition of 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide hydrochloride (which will hereinafter be abbreviated as "EDC·HCl") (331 mg, 1.73 mmol), 1-hydroxybenzotriazole (which will hereinafter be abbreviated as "HOBt") and 4-dimethylaminopyridine (which will hereinafter be abbreviated as "DMAP") under stirring at room temperature. The reaction mixture was further stirred overnight at room temperature. The reaction mixture was diluted with ethyl acetate. The diluted mixture was then washed with saturated brine, dried over anhydrous magnesium sulfate and distilled under reduced pressure to remove the solvent. The residue was purified by chromatography on a silica gel column, whereby from chloroform-methanol (10:1, v/v) eluate fractions, methyl 4-((4S)-fluoro-1-(2-phenylamino-6-benzoxazolylacetyl)-(2S)-pyrrolidinylmethoxy)benzoate (560 mg, 96%) was obtained as a pale brown powder.

4-(1-(2-(2-Methylphenylamino)-6-benzoxazolylacetyl)-(4S)-fluoro-(2S)-pyrrolidinylmethoxy)cyclohexanecarboxylic acid, Isomer G and Isomer H:

(Step 1) Synthesis methyl 4-(N-carbobenzoxy-(4S)-fluoro-(2S)-pyrrolidinylmethoxy)cyclohexanecarboxylate, Isomer A and Isomer B

[0350]

[0351] Methyl 4-((4S)-fluoro-(2S)-pyrrolidinylmethoxy)cyclohexanecarboxylate (529 mg, 2.04 mmol) and carbobenzoxy chloride (30 to 35% in toluene, 1.21 ml, 2.04 mmol) were dissolved in methylene chloride (20 ml). Under stirring, a saturated aqueous solution of sodium bicarbonate (5 ml) was added at room temperature. The reaction mixture was further stirred for 5.5 hours at room temperature. The reaction mixture was poured in water (20 ml) and the mixture was extracted with ethyl acetate. The extract was then dried over anhydrous sodium sulfate and distilled under reduced pressure to remove the solvent. The residue was purified by chromatography on a silica gel column, whereby from hexane-ethyl acetate (2:1) eluate fractions, methyl 4-(N-carbobenzoxy-(4S)-fluoro-(2S)-pyrrolidinylmethoxy)cyclohexanecarboxylate (648 mg, 85%), that is, a mixture of two diastereomers was obtained as a colorless oil. Since the mixture was separable into two diastereomers by medium-pressure chromatography on a silica gel column, from hexane-ethyl acetate (3:1) eluate fractions, two isomers were separated.

(Step 1) Synthesis of N-tert-butoxycarbonyl-(4S)-fluoro-(2S)-prolinal

[0463]

[0464] In methylene chloride (50 ml) was dissolved N-tert-butoxycarbonyl-(4S)-fluoro-(2S)-pyrrolidinylmethanol (1.22 g, 5.57 mmol). Under stirring at room temperature, 1,1,1-triacetoxy-1, 1-dihydro-1,2-benziodoxol-3 (1H) -one (Dess-Martin Periodinate, 2.84 g, 6.69 mmol) was added to the resulting solution in portions. After completion of the addition, the reaction mixture was stirred further for 2 hours at room temperature. The insoluble matter was filtered off under reduced pressure and then the filtrate was distilled under reduced pressure to remove the solvent. Ether was added to the residue. After filtering off the insoluble matter, the filtrate was distilled under reduced pressure. (Step 1) Synthesis of ethyl (4-amino-2-fluoro-5-methoxyphenyl)acetate

[0836]

[0837] To 1,2-difluoro-4-methoxybenzene (5 g, 34.7 mmol) was added concentrated H_2SO_4 (9.25 ml, 174 mmol). Concentrated HNO_3 (2.64 ml, 34.7 mmol) was added dropwise under stirring at 0°C . After stirring for 3 hours at room temperature, the reaction mixture was poured into ice water, followed by extraction with ethyl acetate. The extract was washed with saturated brine, dried over anhydrous magnesium sulfate and distilled under reduced pressure to remove the solvent. The residue was dissolved in DMF (100 ml). Under stirring at 0°C , sodium hydride (4.16 g, 104 mmol) was added in portions. After the reaction mixture was stirred at the same temperature for 15 minutes, a solution of ethyl tert-butyl ethyl malonate (6.57 ml, 34.7 mmol) in DMF (50 ml) was added dropwise in portions thereto. After completion of the dropwise addition, stirring was conducted at room temperature for 18 hours. The reaction mixture was poured into ice water - an aqueous ammonium chloride solution, followed by extraction with ethyl acetate. The extract was washed with saturated brine, dried over anhydrous magnesium sulfate and distilled under reduced pressure to remove the solvent. The residue was added with methylene chloride - trifluoroacetic acid (100 ml, 1:1, v/v), followed by heating under reflux for 18 hours. After cooling to room temperature, the reaction mixture was distilled under reduced pressure to remove the solvent. An iron powder (6.2 g, 0.11 mol) was added to the residue and the mixture was sonicated for 5 minutes. To the reaction mixture were added methanol/water (175 ml, 1:4), sodium acetate (4.7 g, 35 mmol) and acetic acid (13.5 ml, 230 mmol), followed by heating under reflux for 3 hours (without using a stirrer). After cooling to

room temperature, the reaction mixture was filtered through Celite under reduced pressure and the filtrate was washed with methanol. The filtrate was distilled under reduced pressure to remove the solvent. The residue was dissolved in ethyl acetate. The ethyl acetate solution was washed with saturated brine, dried over anhydrous magnesium sulfate, and distilled under reduced pressure to remove the solvent. The residue was purified by silica gel column chromatography (middle pressure chromatography system YAMAZEN YFLC-5404, hexane/ethyl acetate 9:1, ϕ 50 mm x 500 mm, 15 ml/min) to give ethyl 4-amino-2-fluoro-5-methoxyphenylacetate (1.75 g, 22%) as a colorless oil.

(Step 1) Synthesis of 5-fluoro-1-methylindole-3-carbaldehyde

[1033]

[1034] In DMF (60 ml) was dissolved 5-fluoroindole-3-carbaldehyde (5.00 g, 30.6 mmol). Under stirring at 0°C , sodium hydride (60% in oil, 1.35 g, 33.7 mmol) was added in portions. After the reaction mixture was stirred at the same temperature for 1 hour, methyl iodide (5.72 ml, 91.9 mmol) was added thereto. The resulting mixture was stirred further at 0°C for 2 hours. A saturated aqueous solution of ammonium chloride was added to the reaction mixture to neutralize the same, followed by extraction with ethyl acetate. The extract was washed with saturated brine, dried over anhydrous magnesium sulfate, and distilled under reduced pressure to remove the solvent. The residue was purified by chromatography on a silica gel column, whereby from ethyl acetate eluate fractions, 5-fluoro-1-methylindole-3-carbaldehyde (5.42 g, 100%) was obtained as a colorless solid.

(Step 1) Synthesis of methyl trans-4-((2S)-pyrrolidinylmethoxy)-1-cyclohexanecarboxylate

[1267]

[1268] Methyl 4-((2S)-pyrrolidinylmethoxy)benzoate (2.0 g, 7.36 mmol) was dissolved in acetic acid-methanol (1:10, 55 ml). To the resulting solution was added rhodium/alumina (1 g), followed by catalytic hydrogenation at room temperature under 3.8 atm for 15 hours. From the reaction mixture, the catalyst was filtered off. The filtrate was distilled under reduced pressure to remove the solvent, whereby methyl 4-((2S)-pyrrolidinylmethoxy)-1-cyclohexanecarboxylate (1.71 g) was obtained as a colorless oil. The resulting compound was dissolved in acetonitrile-water (1:1, 40 ml). To the resulting solution were added triethylamine (1.5 ml, 10.6 mmol) and di-tert-butyl dicarbonate (1.7 g, 7.80 mmol) and the resulting mixture was stirred at room temperature for 15 hours. The reaction mixture was diluted with ethyl acetate (300 ml). The diluted mixture was washed successively with 1N HCl (100 ml) and saturated brine (100 ml), dried over anhydrous magnesium sulfate, and distilled under reduced pressure to remove the solvent, whereby methyl

4-(1-(tert-butoxycarbonyl)-(2S)-pyrrolidinylmethoxy)-1-cyclohexanecarboxylate (2.26 g) was obtained as a colorless oil. The resulting oil was dissolved in methanol (50 ml). To the resulting solution was added sodium methoxide (1.07 g, 19.9 mmol), followed by heating under reflux for 15 hours. The reaction mixture was cooled and poured in 1N HCl (100 ml), followed by extraction with chloroform (2 x 100 ml). The extract was dried over anhydrous magnesium sulfate and distilled under reduced pressure to remove the solvent. The oily residue was dissolved in methanol/benzene (1:4, 60 ml) and under stirring at room temperature, (trimethylsilyl)diazomethane (a 2M-hexane solution) was added in portions to the resulting solution until the disappearance of carboxylic acid was confirmed by TLC. The resulting mixture was distilled under reduced pressure to remove the solvent to give a 1:1 cis-trans mixture of methyl 4-((2S)-pyrrolidinylmethoxy)-1-cyclohexanecarboxylate as an oil. The resulting mixture was purified by flash column chromatography (Biotage) whereby from hexane-ethyl acetate (4:1) eluate fractions, the trans-isomer was obtained. The trans isomer was dissolved in trifluoroacetic acid (5 ml) and methylene chloride (5 ml). The mixture was stirred at room temperature for 15 minutes. From the reaction mixture, the solvent was distilled off under reduced pressure. The residue was neutralized with a saturated aqueous solution of sodium bicarbonate, followed by extraction with chloroform (200 ml). The extract was dried over anhydrous magnesium sulfate and distilled under reduced pressure to remove the solvent, whereby methyl trans-4-((2S)-pyrrolidinylmethoxy)-1-cyclohexanecarboxylate (504 mg) was obtained as a pale yellow oil.

[1310] In methanol/acetic acid (10/1, 55 ml), methyl 4-(N-tert-butoxycarbonyl-(5S)-methyl-(2S)-pyrrolidinylmethoxy)benzoate (3.27 g, 9.34 mmol) and 5% rhodium-alumina (0.52 g) were stirred at room temperature for 18 hours under a hydrogen gas of 20 atm. From the reaction mixture, the catalyst was filtered off and then, the solvent was distilled off under reduced pressure. The residue was purified by chromatography on a silica gel column, whereby from hexane/ethyl acetate (3/1) eluate fractions, methyl 4-((5S)-methyl-(2S)-pyrrolidinylmethoxy)cyclohexanecarboxylate (1.74 g, 52%) was obtained as a colorless oil. Under a nitrogen gas stream, methyl 4-((5S)-methyl-(2S)-pyrrolidinylmethoxy)cyclohexanecarboxylate (1.73 g, 4.87 mmol) was dissolved in methanol (50 ml). To the resulting solution was added sodium methoxide (800 mg, 14.6 mmol) and the mixture was stirred for 24 hours. After cooling, 1N HCl was added and the resulting mixture was concentrated under reduced pressure. The concentrate was extracted with a chloroform/methanol (10/1) mixture. The extract was dried over anhydrous sodium sulfate and distilled under reduced pressure to remove the solvent. The residue was dissolved in benzene/ methanol (5/1, 30 ml). Under stirring at 0°C, trimethylsilyldiazomethane (a 2.0M hexane solution) was added dropwise to the solution. After completion of the dropwise addition, the reaction mixture was stirred at room temperature for 2 hours. The reaction mixture was then distilled under reduced pressure to remove the solvent, and the residue was purified by flash column chromatography using silica gel, whereby from hexane/ethyl acetate (8/1) eluate fractions, methyl trans-4-(N-tert-butoxycarbonyl-(5S)-methyl-(2S)-pyrrolidinylmethoxy)cyclohexanecarboxylate (700 mg, 40%) was obtained as an oil. The product was dissolved into methylene chloride (30 ml), and trifluoroacetic acid (10 ml) was added to the resulting solution. The mixture was stirred at room temperature for 7 hours. From the reaction mixture, the solvent was distilled off under reduced pressure. To the residue was added a saturated aqueous solution of sodium bicarbonate, followed by extraction with chloroform/methanol (10/1). The extract was dried over anhydrous sodium sulfate, and distilled under reduced pressure to remove the solvent to give methyl trans-4-(5S)-methyl-(2S)-pyrrolidinylmethoxy)cyclohexanecarboxylate (502 mg, 100 %) as a pale yellow oil.

[1476]

[1477] Methyl trans-4-(1-tert-butoxycarbonyl-(2S)-hydroxymethyl-(4R)-pyrrolidinyl)oxy)cyclohexanecarboxylate (247 mg, 0.683 mmol) was dissolved in DMF (5 ml). To the resulting solution was added sodium hydride (60% in oil, 55 mg, 1.37 mmol) in portions under stirring at 0°C in a nitrogen gas stream. After the reaction mixture was stirred at the same temperature for 30 minutes, methyl iodide (85 μ l, 1.37 mmol) was added thereto. Stirring was conducted further at the same temperature for 4 hours. Sodium hydride (60% in oil, 55 mg, 1.37 mmol) and methyl iodide (85 μ l, 1.37 mmol) were added and the mixture was stirred at room temperature for 14 hours. The reaction mixture was poured in water, followed by extraction with chloroform. The extract was washed with a saturated aqueous solution of sodium bicarbonate and saturated brine, dried over anhydrous sodium sulfate, and distilled under reduced pressure to remove the solvent. The residue was purified by chromatography on a silica gel column, whereby from n-hexane/ethyl acetate (2/1) eluate fractions, trans-4-(1-tert-butoxycarbonyl-(2S)-methoxymethyl-(4R)-pyrrolidinyl)oxy)cyclohexanecarboxylate (260 mg, 100%) was obtained as a colorless oil.

Test 1: In vitro evaluation of test compounds

In vitro evaluation test (1)

[1624] CHO cells forcedly expressed by the transduction of integrins $\text{ha}\alpha_4$ and β_1 were seeded in a Coster 3599 plate (3×10^4 cells/100 μl /well) and they were cultured for 2 days. After the medium was washed with buffer A twice, 50 μl /well of Eu^{3+} -hVCAM-1 DID7-IgG diluted to 2 nM with an assay buffer ** was added. To the resulting well was added 50 μl /well of a test compound diluted with 2% DMSO-assay buffer (in the presence or absence of 6% human serum albumin) (to a well subjected to Scatchard analysis was added a solution diluted in another manner). After stirring for 5 minutes on a plate mixer, the plate was allowed to stand at room temperature for 1 hour. Then, the plate was washed four times with the buffer A and added with 100 μl /well of an enhancement reagent (DELFA). The plate was shaken for 5 minutes on a plate mixer, followed by measurement of fluorescence intensity by a time-resolved

fluorometer (DELFA Wallac). From the binding ratio available by the following calculation formula: $((F_T - F_{NS}) - (F_I - F_{NS})) / (F_T - F_{NS}) \times 100$, the IC_{50} (concentration inhibiting 50% of binding of CHO cells with hVCAM-1 D1D7-IgG) of the test compound was determined. In the above formula, F_T means the fluorescence intensity of the well free of the test compound, F_{NS} means the fluorescence intensity of the well free of the test compound and anti- α_4 antibody (SG/73), and F_I means the fluorescence intensity of the well containing the test compound. The K_d indicating the binding strength and B_{max} (maximum binding) were estimated within a range of 0.06 to 20 nM in accordance with the Scatchard analysis method. The results are shown in Table 1.

[1625] The value K_i was calculated based on:

$$K_i = \frac{IC_{50}}{1 + \frac{[L]}{K_d}}$$

((L) means a ligand concentration).

In vitro Evaluation Test (2)

[1626] In a 96-well microplate, hVCAM-1 D1D7-IgG (600 ng/ml in TSM) was immobilized at 4°C (50 μ l/well). After blocking by the addition of 100 μ l/well of a 2% BSA-TSM solution, 150 μ l/well (2.1×10^5 /well) of Jurkat cells labeled with BCECF-AM and 50 μ l/well of a test compound were added and the plate was allowed to stand at 37°C for 1 hour.

The test compound was adjusted to have a final concentration of 0.1 ng/ml to 100 ng/ml (0.5% DMSO). The well was filled with the below-described medium and sealed with a plate seal (product of Sumitomo Bakelite). The plate was then turned inside out and allowed to stand at room temperature for 30 minutes. Then, unbound cells were removed. After suction of the medium, the cells were solubilized with a 0.1% NP-40 solution and fluorescence intensity was measured by a fluorescence reader (excited at 485 nm/measured at 550 nm). From the binding ratio available by the following formula: $((F_T - F_{NS}) - (F_I - F_{NS})) / (F_T - F_{NS}) \times 100$, the IC_{50} (concentration inhibiting 50% of the binding of hVCAM-1 D1D7-IgG with Jurkat cells) of the test compound was determined. In the above equation, F_T means the fluorescence intensity of the well free of the test compound, F_{NS} means the fluorescence intensity of the well free of the test compound and hVCAM-1 D1D7-IgG, and F_I means the fluorescence intensity of the well containing the test compound.

Test 2: In vivo evaluation of test compounds Transmigration test of eosinophils in the mice actively sensitized with ascaris (*Ascaris suum* antigen in pigs):

[1627] It has been reported that eosinophil transmigration was induced by active sensitization with ascaris (Int. Arch. Immunol., 108, 11-18(1995)). Test compounds were evaluated in accordance with the method described in this literature. Test compounds were each orally or subcutaneously administered two or three times a day. The total cell count and eosinophil count in BALF 48 hours after sensitization were calculated and effects were compared between the test-compound-administered group and a test-compound-free group.

Inhibitory action against pleurisy of rat sensitized with Compound 48/80:

[1628] By intrapleurally inoculating 7-week-old male CD/IGS rats (Charles River Japan) with 50 µg of Compound 48/80 (Sigma), pleurisy was caused. The pleural exudate for 24 hours was collected together with the buffer and the number of eosinophils in the exudate was counted. The test compound was orally or subcutaneously administered once or twice by using a proper solvent such as 0.5% MC (aqueous solution of methyl cellulose). Effects of it were compared with those of a test-compound-free group.

Test 3: Evaluation of oral bioavailability by mouse bioassay

[1629] A test compound was suspended or dissolved in a proper administration medium to give a concentration of 1 mg/ ml. To 7 to 9 week old female Balb/ C mice, 10 mg/ kg of the resulting suspension or solution was orally administered. Fifteen minutes after the administration, blood was collected from the postcava under anesthesia with ether and the serum was separated from it. The concentration of each test compound was determined by estimating the serum level from a calibration curve obtained with VCAM-1/VLA-4 inhibitory activity as an index or measuring the concentration by using LC/MS/MS. The results are shown in Table 2.

Industrial Applicability

[1631] The invention compounds or salts thereof selectively inhibit the binding of cell adhesion molecules to VLA-4 and exhibit high oral bioavailability so that they are usable as a preventive or remedy for various diseases mediated by migration and adhesion of leukocytes such as inflammatory diseases, autoimmune diseases, metastasis, bronchial asthma, rhinostenosis, diabetes, arthritis, psoriasis, multiple sclerosis, inflammatory intestinal diseases, and rejection upon transplantation. They are highly effective when orally administered and can be administered for a long period of time so that they are of high clinical utility.

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 18
because they relate to subject matter not required to be searched by this Authority, namely:
Claim 18 pertains to a method for treatment of the human body by therapy.
(See extra sheet.)
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)This International Searching Authority found multiple inventions in this international application, as follows:
(See extra sheet.)

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☒ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest ☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.

Continuation of Box No. II of Continuation of first sheet (1)

The chemical structures common to the compounds represented by the structural formula in claim 1 are only nitrogen attached to X and oxocarbonyl at the end of M, and the other moieties are changeable. As described above, many compounds having such chemical structures are publicly known, and the chemical structures are therefore not important ones. Thus, this application does not comply with the requirement of unity of invention.

Additionally, the structural formula set forth in claim 1 includes a great many compounds having various chemical structures, but the compounds disclosed concretely in the description are limited only to those having specific chemical structures. As described above, many compounds having the chemical structures are publicly known and it is therefore extremely difficult to search over the whole scope of claim 1 and cite all of the prior art documents. Accordingly, this international search has been carried out with priority given to the compounds disclosed concretely in the description.
